SOV/4035

Vaynshteyn, L.A., and V.D. Zubakov

Vydeleniye signalov na fone sluchaynykh pomekh (Signal Separation
Against a Background of Random Interference) Moscow, Izd-vo
"Sovetskoye radio," 1960. 446 p. Errata slip inserted. No. of
copies printed not given.

Ed.: N.D. Ivanushko; Tech. Ed.: A.A. Sveshnikov.

PURPOSE: This monograph is intended for physicists and engineers
working with fluctuation noise and interference problems. It
may also be used as a textbook by students and aspirants studying
statistical radio physics, information theory, and random processes
in radio devices.

COVERAGE: The monograph contains an exposition of statistical theory
of optimal receivers which not only detect signals having various
characteristics against a background of random noise, but also
measure the parameters of such signals. The theory of linear

Card 1/9

Signal Separation (Cont.)

SOV/4035

filters, filters which separate useful processes from interfering ones, is presented in the introduction. Major attention is paid to radar problems. The book also describes some new experiments carried out by the authors. Parts I and III and Ch. VII of Part II were written by L.A. Vaynshteyn. V.D. Zubakov wrote the rest of Part II except Ch. VIII, which was written jointly by both authors. The authors thank Yu.B. Kobzarev. There are 48 references: 29 Soviet (8 of which are translations), 18 English, and 1 German.

TABLE OF CONTENTS:

Foreword	3
PART I. STATISTICAL THEORY OF OPTIMAL LINEAR FILTERS	
Ch. I. Basic Concepts of Random Processes Filtration Theory	7
1. Stating the problem	7
2. Integral equation of optimal linear filter	14
3. Correlation functions and spectrum intensities	
4. Frequency response curves of linear filters and their corresponding operators	24

Synthesis and Investigation of Highmolecular
Tertiary Amines and Quaternary Ammonium Compounds S/ 90/3/102/006/006/012
on the Basis of the Copolymers of 2-Methyl-5-vinyl
Pyridine With Various "Interlacing" Agents B015/B064

obtained subjected to different physico-chemical tests (anion exchange, chemical stability, water absorption, swelling in organic solvents etc.). On heating, or irradiating 2-methyl-5-vinyl pyridine with 0.4% of benzoyl peroxide only with a quartz lamp of the NPK -2 (PRK-2) type, the reaction products obtained were only soluble in organic solvents. Copolymerization at 70-80°C (end at 100°C) and a duration of 4-5 h of 100 parts by weight of 2-methyl-5-vinyl pyridine and 4 parts by weight of divinyl benzene besides 0.4 parts by weight of benzoyl peroxide in suspension resulted in a solid copolymer, insoluble in organic solvents, with weakly alkaline character, and anion exchanger properties (Table 1). Alkylation was carried out in the same cylindrical glass reaction vessel as copolymerization, with benzyl chloride, para-toluene sulphonate, ethyl iodide and methyl iodide being used. Products of benzylation and methylation with para-toluene sulfo acid methyl ester had the highest capacity of exchange. The degree of alkylation rises with the reaction time. An action of strong acid solutions (5 N and 9 N HNO₃, H₂SO₄) and lyes (1 N and 9 N NaOH) upon the anion exchangers in the form of tertiary

PURPOSE: This book is intended for production engineers and for scientific and technical personnel at design offices of industrial plants and research institutes engaged in the designing and production of vibratory machines.

COVERAGE: The book presents the elements of the theory of compaction by vibratory machines. Experience gained in the use of shallow and deep vibratory machines is summarized. Recommendations are given for eliminating individual defects of machines. Questions on the theory of vibratory machines are elucidated, and optimum

TITLE: The smelting of rimming steel in 80-ton electric furnaces with con-
tinuous pouring

PERIODICAL: Stal', no. 5, 1962, 420 - 425

TEXT: The industrial-scale electric smelting of rimming steel is carried out in furnaces with a rated capacity of 80 tons and an actual capacity of 90 - 95 tons, (transformer capacity: 25,000 kW, electrode-diameter: 555 mm, depth of the bath: 1000 mm). Tests have shown that one of the most important conditions of this process is the oxidation of the metal before tapping which determines its uniform rimming in the ingot mold. The oxygen quantity involved in the process depends mainly on the carbon content of the metal and the ferric oxide content of the slag. This, in turn, is conditioned by the quantity of ore added to the charge and the basicity of the slag. For slags with a basicity of 3.0 - 5.0 and at metal temperatures of 1635 - 1645°C, the average value of FeO_{total} was 24.1%; [Abstracter's note: subscript total is the translation of the Russian subscript

The smelting of.....

объект - (obshchiy)], at temperatures above 1660°C: 18.2%. To obtain the required oxidation during rimming of the metal three methods were used: a) adding ore, b) with oxygen and ore, c) with oxygen alone. Generally method b) is applied, ensuring quick heating of the bath, a higher oxidation rate of carbon (0.25 - 1.0% C per hour) and a ferric oxide content of the slag of 20.3%. The optimum metal temperature at the beginning of oxygen blowing was found by tests to be 1,570 - 1,580°C. The optimum degree of metal oxidation ensuring a uniform rimming in the mold, can be obtained when the slag contains 15 - 23% FeO_{total} before reduction. Oxidation and rimming can be promoted by adding 50 - 200 g/ton aluminum in the ladle, depending on the carbon content and oxidation of the slag. Desulfurization of the metal takes place most intensively (before slag tapping) at a slag basicity of 2.5 - 3.0. In this case it will be 0.011% of the smelt (average value). When electro-smelting of rimming steel is combined with continuous pouring, the charge must be composed so that the carbon content of the smelting metal is 0.10 - 0.20% higher than prescribed for the given grade. The charge usually consists of 80 tons iron-steel scrap, 5 tons scrap and waste from the converting shops and 5 tons pig iron; the first batch (55 - 65% of the charge) is molten in 1 - 1.5 hours, then 1.5 - 2.5% ore is added to obtain a 13 - 20% FeO_{total} content of the slag, then lime or limestone (4 - 5% or 7 - 8% respectively).

The smelting of.....

ly) is added to get a slag basicity of 2.5 - 3.0. Pig iron stabilizes the carbon content during smelting and improves desulfurization at the beginning of rimming. Oxygen (98.5 - 99.2% pure) is blown through the bath twice, for 3 - 15 minutes, at a pressure of 10 - 13 atm. The average oxygen consumption per smelt is 3 - 8 m³/ton. The temperature upon the first oxygen blowing should be over 1560°C, before the second blowing over 1580°C, to prevent over-oxidation of the metal. The composition of steel grades produced by the method is: (in %)

	C	Mn	S	P
Cr.3Kп (St.3kp)	0.17	0.40	0.040	0.022
Cr.2Kп (St.2kp)	0.11	0.40	0.034	0.012
Cr.1Kп (St.1kp)	0.09	0.35	0.035	0.011

Continuous pouring is carried out with double-channel, vertical type equipment, for casting 150 x 620, 150 x 780 and 170 x 1040 mm ingots. Close attention was paid to the ladle-spout lining. The best results were obtained by using for the ladle and intermittent ladle casings with a high aluminum oxide content, which last longer and ensure a controlled flow of a quantity of 90 tons of molten steel. The pouring rates are: for 150 x 620 mm ingots 0.8 - 0.9 m/min, for 150 x 780 mm ingots 0.7 - 0.8 m/min and for 170 x 1040 mm ingots 0.5 - 0.6 m/min. Pouring 90 tons of metal through two channels requires 65 - 70 minutes. The rate of

A054/A127

The smelting of.....

pouring is limited by the shortness of the secondary cooling sector (6.5m), where the metal solidifies. The rimming of the steel in the mold, in case of medium-carbon grades, can be promoted by adding aluminum, in the case of medium-carbon grades by blowing oxygen into the metal stream after the intermittent ladle. The macrostructure of continuously poured, electro-smelted steels was studied with 110 templates taken from 67 heats. Due to the low iron content and inadequate addition of aluminum in the ladle, the metal with a carbon content above 0.13% rims weakly in the mold and much too thin a skin forms. In this case, blowing oxygen will intensify rimming and a normal skin, 10 - 25 mm thick, will be obtained. Other defects often encountered in this kind of ingots are blisters in the skin, 0.5 - 3.0 mm in diameter, at a depth of 1 - 5 mm below the surface, and also beads and lateral and longitudinal cracks. Lateral cracks can be prevented by closely controlling the metal oxidation and improving the mold-coating. Longitudinal cracks are less frequent, mainly owing to the delayed shrinkage of the thinned sectors of the solidifying skin in the mold. Rimming steel ingots are hot-rolled on the 1200-mm mill, with universal roughing, two-high stand and reversing-finishing four-high stand, with coils heated in the furnace. To promote the sintering of gas-blisters, the reductions are increased (170 x 1040 mm slabs are reduced with 9 passes instead of 11, 150 x 620 mm slabs with 5 passes instead of 7).

Card 4/5

The smelting of

S/133/62/000/005/004/008
A054/A127

The slab-heating temperature was raised from 1260 - 1270 to 1280 - 1310°C. Sheets, 13 - 14 mm and 2 - 3 mm thick are rolled from these slabs. At the "Zaporozhstal" Plant the rate of consumption of the metal charge was 1.262 ton/ton of flawless product in 1960; for the new process this parameter was 1.127 - 1.135 ton/ton of flawless product. Smelting time was reduced to 4 $\frac{1}{4}$ hours; the electric power required is 500 - 550 kW-h/ton of flawless steel. The application of minimum 80-ton capacity electric furnaces and continuous pouring is advisable where cheap open-hearth scrap and electric power are available. This increases production by 8 - 12% with a minimum capital outlay. There are 3 figures. The reference to the English-language publication reads as follows: Reinartz, L., Barnes, H., Iron and Steel Engineer, no. 1, 1954.
